

Crypto market-making scenario report

PEPEUSDT experiments, execution assumptions, and what the results support.

Prepared 8 October 2026 · dates in UTC unless stated · USD-equivalent P&L

01 / FINDINGS

Fill assumptions drive the apparent edge.

348

Saved Tardis run outputs
with overlapping controls

2 days

September 1 & October 1
not 348 independent samples

\$70,000

Starting capital per daily run
PEPE-only allocation

The strongest modeled result was fast, long-only midpoint quoting without the one-tick minimum distance under touch fills. Requiring one-tick penetration on most orders largely removed that profitability. This is evidence of **execution-model sensitivity**, not a demonstrated live trading edge.

- **Refresh and shorts:** 20-second, long-only, minimum OFF led the touch-fill grid on both days. Fast, tight quoting with venue-style shorts performed poorly.
- **Penetration:** at 20 seconds, midpoint long-only mean daily P&L fell from **+\$7,306** under touch fills to **-\$673** at $p=0.9$ and **-\$1,177** at $p=1$.
- **Reference price:** midpoint versus close was mixed under touch fills. Latest close outperformed midpoint in all 12 day/refresh pairs at $p=0.9$, within the matched reference experiment.
- **Latency:** delays did not consistently hurt simulated P&L. Some delayed quotes were already marketable against the current book; the model did not implement their rejection or taker execution.

The two dates were chosen because free Tardis samples were available. Signal parameters were not optimized per refresh interval. Results should not be generalized to other dates or treated as live-return forecasts.

02 / EXPERIMENT CONTRACT

What was held fixed—and what changed

Study	Run outputs	Market sample
Refresh × minimum distance × shorts		48 Sep 1 & Oct 1, 2026
Penetration $p=0.5$ / 1		24 Sep 1 & Oct 1, 2026
Penetration $p=0.8$		12 Sep 1 & Oct 1, 2026
Reference price — touch fills		36 Sep 1 & Oct 1, 2026
Reference price — $p=0.9$		36 Sep 1 & Oct 1, 2026

Study	Run outputs	Market sample
Feed latency — touch / p=0.9		192 Sep 1 & Oct 1, 2026

“Run outputs” counts saved simulations, including repeated zero-delay and midpoint controls. Each daily run resets capital, inventory and orders. Two-day figures below are arithmetic means of independent daily P&Ls, not compounded returns.

Capital / inventory	\$70,000 PEPE budget; fixed startup lot worth \$3,500; nominal gross inventory cap \$49,000. Allocation is not 100% continuously invested.
Price / quantity precision	PEPE tick 0.00000001; integer quantity step; \$1 minimum notional.
Signal settings for recent Tardis tests	20s forecast horizon; 10s signal decay; alpha EWMA half-life 10s; volatility EWMA half-life 30s; 1h candle warmup; one additional second of feature lag.
Refresh intervals	20s, 30s, 60s, 180s, 300s, 600s. Forecast/decay/EWMA settings stay fixed across intervals.
Fees and terminal treatment	Spot maker 5 bps; short opening/closing 10 bps; terminal shorts closed; remaining spot marked with a 10-bps exit allowance. Main Tardis tables include these modeled final costs.
Short mechanics	Collateralized venue-style shorts: short asks when no spot is held; local cover conditions execute at the next eligible candle open. Not symmetric maker-only two-sided MM.
What the simulator omits	Queue position, volume-constrained fills, own-order market impact, live API scheduling, and current-venue rejection/taker behavior for orders already crossing on arrival.

Three settings that must not be confused

Minimum quote distance

When ON, each quote must be at least one tick from its reference before outward rounding. OFF retains tick rounding and the 2-bps minimum distance; it does not mean zero spread.

Fill penetration

A buy fills only if the candle low reaches the limit minus one tick; a sell requires the high to reach the limit plus one tick. Zero ticks allows touch fills.

Penetration probability p

The one-tick requirement is assigned once per order with probability p. Otherwise that order allows touch fills. This is **not** a probability of filling after penetration. Fractional-p runs use seed 20261008, one realization each.

03 / DATA AND CAUSAL TIMING

Full-day Tardis history versus sparse CoinAPI windows

Tardis supplied **197,371** PEPEUSDT quote updates for September 1 and **198,171** for October 1. Binance one-second candles supplied signals, candle fill checks and valuation, with the previous hour used for warmup. Binance archive checksums matched.

Midpoints use the latest Tardis observation received before the decision, not a future quote. The two-second age rule passes roughly **81–89%** of refreshes in the no-added-delay grid. Older books suppress quoting. An unchanged quote older than two seconds does not itself prove an outage: the age cutoff is an explicit strategy assumption.

Day	Refresh (s)	Decisions	Eligible	Skipped	Eligible %
2026-09-01		20	4,320	3,814	50688.29%
2026-09-01		30	2,880	2,562	31888.96%
2026-09-01		60	1,440	1,257	18387.29%
2026-09-01		180	480	420	6087.50%
2026-09-01		300	288	255	3388.54%
2026-09-01		600	144	126	1887.50%
2026-10-01		20	4,320	3,814	50688.29%

Day	Refresh (s)	Decisions	Eligible	Skipped	Eligible %	
2026-10-01		30	2,880	2,521	359	87.53%
2026-10-01		60	1,440	1,247	193	86.60%
2026-10-01		180	480	418	62	87.08%
2026-10-01		300	288	247	41	85.76%
2026-10-01		600	144	117	27	81.25%

Our earlier CoinAPI download contained only 5,724 records from two-second windows before 432 ten-minute decisions. It was sufficient for that sampling schedule but supported only 386 of 12,960 decisions after switching to a 20-second refresh.

04 / REFRESH × QUOTE DISTANCE × SHORTS

Touch-fill results

Net P&L after trading fees and modeled terminal costs. Fill penetration is zero in every cell.

2026-09-01 · independent UTC day

Refresh	Long only · min ON	Long only · min OFF	Shorts ON · min ON	Shorts ON · min OFF
20s	+\$1,319.77	+\$8,359.68	+\$1,525.73	-\$2,976.56
30s	+\$1,530.05	+\$6,675.93	+\$1,736.33	-\$793.54
60s	+\$1,601.87	+\$3,853.97	+\$1,855.74	-\$1,358.78
3m	+\$1,454.76	+\$1,640.95	+\$1,775.91	-\$199.91
5m	+\$1,024.24	+\$1,112.13	+\$1,406.52	+\$712.34
10m	+\$388.71	+\$321.69	+\$538.32	+\$418.43

2026-10-01 · independent UTC day

Refresh	Long only · min ON	Long only · min OFF	Shorts ON · min ON	Shorts ON · min OFF
20s	+\$2,649.02	+\$6,252.71	-\$46.89	-\$9,115.69
30s	+\$2,367.47	+\$5,113.91	-\$244.46	-\$8,047.13
60s	+\$2,521.06	+\$3,858.02	-\$137.42	-\$4,311.08
3m	+\$1,657.67	+\$2,066.50	-\$922.80	-\$1,557.86
5m	+\$2,092.07	+\$1,134.76	+\$13.98	-\$668.31
10m	+\$1,399.54	+\$584.16	+\$197.39	+\$250.92

For example, on October 1 the 20-second minimum-OFF case produced +\$6,252.71 long-only but −\$9,115.69 with shorts. Fees rose from \$7,863.97 to \$14,094.89. This compares different inventory paths and venue-style short costs, not merely an extra symmetric quote.

05 / FILL-MODEL SENSITIVITY

The fast-refresh result is fragile to penetration.

All cells: midpoint reference, long-only, minimum quote distance OFF. “Touch” has zero penetration ticks. Other columns set one penetration tick with the stated per-order probability. Fractional-p runs are not Monte Carlo averages.

20-second midpoint quoting: profits depend strongly on the fill assumption

2026-09-01

Refresh	Touch (p=0)	p=0.5	p=0.8	p=0.9	p=1.0
20s	+\$8,359.68	+\$3,434.93	+\$99.27	-\$403.16	-\$943.28
30s	+\$6,675.93	+\$2,778.97	+\$575.68	-\$693.92	-\$1,057.85
60s	+\$3,853.97	+\$1,462.62	-\$259.25	-\$1,046.10	-\$1,182.37
3m	+\$1,640.95	+\$369.43	-\$477.22	-\$755.48	-\$896.60
5m	+\$1,112.13	+\$500.10	+\$101.43	-\$271.82	-\$667.34
10m	+\$321.69	+\$80.51	-\$256.86	-\$557.53	-\$524.46

2026-10-01

Refresh	Touch (p=0)	p=0.5	p=0.8	p=0.9	p=1.0
20s	+\$6,252.71	+\$1,793.49	+\$123.30	-\$942.34	-\$1,410.46
30s	+\$5,113.91	+\$1,223.49	-\$199.87	-\$1,354.84	-\$1,311.42
60s	+\$3,858.02	+\$1,459.49	+\$99.60	-\$507.30	-\$893.45
3m	+\$2,066.50	+\$960.86	+\$53.53	-\$328.17	-\$497.51
5m	+\$1,134.76	+\$632.54	+\$473.77	+\$269.59	+\$314.22
10m	+\$584.16	+\$394.52	+\$324.20	+\$281.15	+\$395.72

p=1 is a conservative *trade-through execution scenario*, not a mathematical worst-case P&L bound. Fewer fills can remove losing entries as well as profitable exits.

06 / MIDPOINT VERSUS CLOSE

No reference price wins under every fill model.

Quote-reference variants: latest midpoint, latest completed close at t-1s, and original lagged close at t-2s. All share the same signals, midpoint-based capacity/passivity checks and quote-age eligibility. Only the formula reference changes. This is not a wholesale replay of the original candle-only implementation.

Delaying information is different from delaying an order.

Added feed delays of 0, 1, 2 and 3 seconds were applied to midpoint, close, alpha and volatility. The latest completed close is t-delay-1s; features end at t-delay-2s. Thus +1s exposes close t-2, while +2s exposes close t-3. Startup anchors also use the latest close available under that delay.

The quote-age allowance is measured at the delayed feed cutoff: a D-second delay permits wall-clock quote age up to D+2s. Keeping a strict two-second wall-clock limit would instead suppress many delayed orders. Order-routing/activation delay remains zero, and cancellation latency is not modeled.

10m		+\$9.33	+\$11.85	+\$64.96	+\$79.95

Why latency can appear beneficial here: stale prices alter rounding, inventory and eligible refreshes. The simulation also permits some quotes that already cross the current market to remain in the candle-fill model. At 20s refresh and +3s delay, the p=0.9 midpoint case submitted 295 already-marketable orders across both days; the close case submitted 75. Those need arrival-time rejection or taker treatment before making live-execution claims.

All zero-delay runs reproduce the earlier matching models and event ledgers exactly. Independent Python calculations verified delayed EWMA values and each penetration assignment.

08 / EARLIER THREE-DAY DIAGNOSTICS

Preserved for context—not a continuous 20-second test.

Window: October 4, 15:01 UTC through October 7, 15:01 UTC. The initial candle-reference comparison produced identical results with minimum distance ON/OFF because its references lay on the tick grid. Actual midpoints introduced half-tick references and different rounded quotes.

The 20-second CoinAPI diagnostics had only 2.98% quote coverage. They typically quoted for 20 seconds, canceled, and waited until the next cached ten-minute window. Inventory stayed exposed between windows. Their profits must not rank continuous 20-second market-

Experiment	Minimum	Shorts	Net P&L	Fills	Coverage
Lagged candle close · 10m · penetration 1	ON	OFF	−\$4,219.18	218	Candle reference
Lagged candle close · 10m · penetration 1	ON	ON	−\$4,256.31	265	Candle reference
Lagged candle close · 10m · penetration 1	OFF	OFF	−\$4,219.18	218	Candle reference
Lagged candle close · 10m · penetration 1	OFF	ON	−\$4,256.31	265	Candle reference
Midpoint · 10m · penetration 1	ON	OFF	−\$2,164.29	97	386 / 432 decisions
Midpoint · 10m · penetration 1	ON	ON	−\$2,073.79	146	386 / 432 decisions
Midpoint · 10m · penetration 1	OFF	OFF	−\$1,916.76	335	386 / 432 decisions
Midpoint · 10m · penetration 1	OFF	ON	−\$1,956.20	399	386 / 432 decisions
Midpoint · 20s · penetration 1	ON	OFF	−\$111.02	1	386 / 12,960 decisions
Midpoint · 20s · penetration 1	ON	ON	−\$182.56	5	386 / 12,960 decisions
Midpoint · 20s · penetration 1	OFF	OFF	−\$28.36	16	386 / 12,960 decisions
Midpoint · 20s · penetration 1	OFF	ON	−\$256.85	46	386 / 12,960 decisions
Midpoint · 20s · touch fills	ON	OFF	−\$92.44	20	386 / 12,960 decisions
Midpoint · 20s · touch fills	ON	ON	+\$4,107.20	32	386 / 12,960 decisions
Midpoint · 20s · touch fills	OFF	OFF	+\$70.42	393	386 / 12,960 decisions
Midpoint · 20s · touch fills	OFF	ON	+\$1,938.96	433	386 / 12,960 decisions

The 10-minute midpoint test skipped 46/432 decisions under the freshness rule. Its comparison against the original candle-reference run also changes quote eligibility, so it is not a pure reference-only comparison.

09 / EARLIER STUDIES IN THIS RESEARCH SEQUENCE

Broader evidence, with different models and windows

These are verified summaries of the preceding experiments. They use different configurations and evaluation windows from the recent Tardis tests. Marked P&L and exit-adjusted P&L are labeled separately; do not combine them into one portfolio track record.

Short-window and PEPE-only replays

Experiment	Start UTC	End UTC	MM P&L (marked)	MM return	MM fills

PEPE venue-style shorts: same 1-day / 2-day windows, one-tick penetration

Days	Shorts enabled	P&L after exit cost	P&L before terminal cost	Fills
1	False	-\$1,080.36	-\$1,034.99	79
1	True	-\$1,167.90	-\$1,122.53	87
2	False	-\$905.65	-\$860.34	191
2	True	-\$1,032.22	-\$986.90	211

The separate October 7, 08:22–09:22 UTC one-hour test had one spot buy and no short trades. Long-only and short-enabled results were identical: –\$10.20 before terminal cost, –\$13.67 after the modeled exit.

30 sampled, non-overlapping weeks

Original fixed three-asset strategy: 85% PEPE, 7.5% BONK, 7.5% 1000CHEEMS within \$70,000 MM capital, plus \$30,000 idle at account level. Original 10-minute refresh, 30-second forecast and 5-minute volatility half-life. Seed 20261007; separate accounts and non-overlapping warmups/windows. Non-overlap does not establish statistical independence.

Metric	Result
Profitable weeks	20 / 30
Mean / median marked weekly return	3.40% / 2.76%
Mean weekly return after terminal cost	3.36%
Worst weekly P&L	–\$6,866.40 (Oct 10–17, 2025)
Best weekly P&L	+\$12,976.29 (Sep 13–20, 2026)
Largest within-week drawdown	41.22%

Historical engine source was frozen at commit 52f0de4 after an external reconciliation-code change was detected during that study. Affected mixed-version runs were excluded and the same dates rerun. Weekly outcomes were not selected by profitability.

88-instrument screen and decay / volatility sweeps

Initial screen: 88 requested instruments, 86 completed, 2 unavailable (OMNI and TON); 16 profitable after fees versus 50 before fees. Median return: -0.379%. Subsequent 3-minute refresh/forecast sweeps compared 30/60/90/180-second decay and 30/300-second volatility half-lives.

Vol half-life (s)	Decay (s)	Instruments	Profitable	Median return	Sum of independent-book P&L
30	30	86	8	-1.13%	–\$10,187.52
30	60	86	9	-1.13%	–\$10,503.86
30	90	86	9	-1.17%	–\$10,204.61
30	180	86	8	-1.23%	–\$9,993.14
300	30	86	8	-1.10%	–\$10,113.13
300	60	86	8	-1.16%	–\$10,510.40
300	90	86	9	-1.17%	–\$10,249.49
300	180	86	8	-1.23%	–\$9,975.60

Independent-book sums are screen aggregates, not the return of one funded portfolio. A shorter volatility half-life did not produce a consistent improvement across decay settings. A volatility-sized, matched-lot prototype and calibration were prepared; no completed performance screen is claimed for that prototype.

Rolling 12-minute coin selection

Ranked prior 12-minute performance, used a daily-equivalent 0.5% threshold, waited three minutes, traded selected coins and liquidated departing names. The common available set contained 86 instruments.

Variant	Net P&L	Fees	Rotation fees	Fills
rotating	-\$997.37		+\$1,184.44	3,980
fixed-original-weights	+\$28.79		+\$852.51	1,363
fixed-equal-weights	-\$178.34		+\$787.65	1,369

Reconciliation timing diagnostic

For the October 10–17, 2025 week, removing API waits changed execution timing substantially. This supports a timing effect; it does not mean the read-only post-run accounting checks manufactured P&L.

Variant	Marked P&L	Fills	Max drawdown	Temporary sync mismatches
weeks	-\$6,866.40	4,552	41.22%	364
timing-check	-\$1,789.21	4,715	26.12%	0

11 / INTERPRETATION AND NEXT STEPS

What these experiments establish

- They establish that modeled outcomes are strongly sensitive to fill rules, quote rounding, short mechanics, and timing.
- They do not establish a safe trading horizon, a guaranteed worst-case P&L, live profitability, or that stale data is beneficial.
- Price horizon, quote refresh and inventory holding period are separate. Calling a 3- or 5-minute strategy “mid-frequency” does not change execution risk.

The proposed opposite-quote / trade-through rule

For a buy at B, best ask ≤ B is an eligibility test; for a sell at A, best bid ≥ A is symmetric. Our existing penetration model instead checks candle trade extremes one tick beyond the limit. These are different events. A historical best bid falling below B can reflect cancellations; it does not prove that a hypothetical buy at B filled. A trade below an already-active bid is stronger evidence under price priority, but adding our quantity can change the historical path.

Before treating a conservative scenario as realistic, model exchange acceptance, cancellation latency, arrival-time post-only rejection or taker execution, partial fills and available volume. Keep p=1 as a stress scenario rather than a lower bound. Evaluate markouts and inventory attribution, then repeat across more dates and seeds.

Report validation and reproducibility

This report was built from saved result files without downloading new market data or changing production configuration. It checked expected row counts and saved validation flags, preserves complete recent-run data, and records SHA-256 hashes of source artifacts. Simulation validations include ledger reconciliation, causal quote/feature timestamps, fill checks, seed-draw checks, and zero-delay regressions where applicable. They test implementation consistency, not economic realism.
